Eastman cellulose esters provide a uniform appearance to cast acrylic sheets for bathtubs, shower enclosures, and spas.
**Application overview**

Cast acrylic sheets are used for outdoor durability and water and UV resistance. They can be found in signs, display shelving, and even countertops. The largest application is in bathtubs, spas, and shower panels. A manufacturing challenge in acrylic sheet production is inconsistent color and blotchiness, which can result in an increased number of rejects and higher production costs for manufacturers.

The challenge in bath application manufacturing occurs when a thin acrylic sheet is pressed into shape by thermoforming and then reinforced on the underside with unsaturated polyester and fiberglass. The thermoformed cast acrylic sheet requires a uniform color on its front and back surfaces. Nonuniform colors can lead to poor color matching when front and back surfaces are interchanged. The cause of these color differences is often related to the flooding and floating of pigments during the curing of the liquid formulation to create a solid cast acrylic sheet. Flooding is the tendency of pigments to rise to the surface during drying and curing. This produces a surface color that is different from the rest of the material. Floating occurs when pigments separate from each other and concentrate in certain areas, resulting in uneven color distribution.

Adding Eastman cellulose acetate butyrate products to formulations increases the pigment dispersion and often alters the rheology of the material. By preventing flooding and floating, Eastman CABs enable a more efficient process that delivers a uniform color consistency that is more pleasing in appearance.

Figure 1 illustrates a simple cast acrylic sheet composition. The blue dots represent a larger-diameter, higher-density pigment. The green dots are a smaller-diameter, less dense pigment. The yellow portion is the polymethacrylate (PMMA) syrup. The viscosity increases as the syrup polymerizes, but gravity can still pull the larger particles to the bottom. As the viscosity continues to increase, the pigments finally lock in place. The result can be an acrylic sheet with one side having a slightly different color/hue. Adding Eastman CAB helps minimize the effect by increasing the pigment dispersion and rheology of the syrup.

**Product-in-use details**

Eastman CAB 381-2 and Eastman CAB 381-20 are often used for cast acrylic sheet applications because they offer high viscosity coupled with good solubility in PMMA syrup. Compatibility with the PMMA syrup is also good. If better compatibility with the syrup is desired, consider Eastman CAB 500-5.

Note: Eastman CAB-381-0.5 is recommended when the methyl methacrylate syrup is polymerized to higher than 8%. In the preceding example formulation, the PMMA syrup formulation was polymerized to less than 8%, consequently CAB 381-20 was used.
Magnified color differences

As shown in the magnified view of the acrylic sheet in Figure 3, the system without Eastman CAB produced a surface with noticeable black specks—evidence of pigment separation. The system containing Eastman CAB produced a surface with no black specks and a uniform gray color.

Figure 3. Cast acrylic sheet with and without Eastman CAB (magnified)

Color differences measured via spectrophotometer

The color change (\(\Delta E\)) between the front and the back surfaces was measured using a Minolta spectrophotometer. The results show low \(\Delta E\) values in the cast acrylic sheet with Eastman CAB, signifying even color distribution. The system without CAB, however, produced a sheet with high \(\Delta E\) values, indicating a dramatic difference in color between the front and back surfaces. This unacceptable appearance can result in an increased number of manufacturing rejects.

Figure 4. \(\Delta E\) value comparison of acrylic sheet with and without Eastman CAB
Conclusion
This study confirms that Eastman CAB considerably reduces flooding and floating of carbon black pigment in a gray cast acrylic sheet, which significantly reduces the color difference between the front and back surfaces. A more uniform sheet color should result in reduced waste from product rejection. Using Eastman CAB 381-0.5 or Eastman CAB 381-20 in cast acrylic sheet formulations allows manufacturers to deliver a higher-quality cast acrylic product with enhanced efficiencies and uniform color consistency that is more aesthetically pleasing.

For help selecting the best cellulose ester for your specific needs, contact your technical service representative or an authorized Eastman distributor.

As the world’s leading supplier of specialty cellulose esters for over 85 years, Eastman has a long history of reliably supplying customers with consistently high-quality products manufactured using advanced processes and controls. With a diverse portfolio of more than 50 cellulose esters—CA, CAB, CAP, and C-A-P—for a variety of applications along with years of formulating experience, our technical experts can provide guidance to help customers select the best cellulose ester or blend to achieve the specific performance desired for their unique application. Over the years, we’ve introduced innovative products that help meet customer needs and market demands—most recently Eastman Solus™ performance additives for high-solids coatings and Eastman membrane material products for membrane filtration. Eastman works with regulatory agencies and industry associations on behalf of our customers to advocate for policies that allow industries to thrive, enabling sustainable innovation.

At Eastman, our goal is to enhance the quality of life in a material way.
